Longest Common Subsequence | Introduction & LCS Length

The longest common subsequence (LCS) problem is the problem of finding the longest subsequence that is present in given two sequences in the same order. i.e. find a longest sequence which can be obtained from the first original sequence by deleting some items, and from the second original sequence by deleting other items.

The problem differs from problem of finding common substrings. Unlike substrings, subsequences are not required to occupy consecutive positions within the original

X: ABCBDAB

Y: BDCABA

The length of LCS is 4

LCS are BDAB, BCAB and BCBA

A Naive solution would be to check if every subsequence of $X[1..m]$ to see if it is also a subsequence of $Y[1..n]$. As there are 2^m subsequences possible of X , the complexity of this solution would be $O(n \cdot 2^m)$.

The LCS problem has an [optimal substructure](#). That means the problem can be broken down into smaller, simple “subproblems”, which can be broken down into yet simpler subproblems, and so on, until, finally, the solution becomes trivial.

1. Let us consider two sequences X and Y of length m and n that both end in the same element.

To find their LCS, shorten each sequence by removing the last element, find the LCS of the shortened sequences, and to that LCS append the removed element. So we can say that

1]) + X[m] if X[m] =
Y[n]

2. Now suppose that the two sequences do not end in the same symbol.

Then the LCS of X and Y is the longer of the two sequences $\text{LCS}(X[1..m-1], Y[1..n])$ and $\text{LCS}(X[1..m], Y[1..n-1])$. To understand this property, let's consider the two following sequences

X: ABCBDAB (*n*
elements)
Y: BDCABA (*m*
elements)

The LCS of these two sequences either ends with a B (the last element of sequence X) or does not.

Case 1: If LCS ends with a B, then it cannot end with a A and we can remove the A from sequence Y and the problem reduces to $\text{LCS}(X[1..m], Y[1..n-1])$.

Case 2: If LCS does not end with a B, then we can remove B from the sequence X and the problem reduces to $\text{LCS}(X[1..m-1], Y[1..n])$. For example,

$\text{LCS}(X[1..m-1], Y[1..n])$

Run
Code

Output:

The length of LCS is 4

The worst case time complexity of above solution is $O(2^{m+n})$.

The worst case happens when there is no common subsequence present in X and Y (i.e. LCS is \emptyset) and each recursive call will end up in two recursive calls.

The LCS problem exhibits [overlapping subproblems](#).

A problem is said to have overlapping subproblems if the recursive algorithm for the problem solves the same subproblem over and over rather than always generating new subproblems.

Let us consider recursion tree for two sequences of length 6 and 8 whose LCS is \emptyset .

This website uses cookies. By using this site you agree to the use of cookies, our policies, copyright terms and other conditions. [Read our Privacy Policy](#)

As we can see, the same sub-problems (highlighted in same color) are getting computed again and again. We know that problems having optimal substructure and overlapping subproblems can be solved by dynamic programming, in which subproblem solutions are memoized rather than computed again and again. This method is illustrated below in C++ and Java

-

C++

```
1  #include <iostream>
2  #include <string>
3  #include <unordered_map>
4  using namespace std;
5
6  // Function to find len
7  // X[0..m-1] and Y[0..n]
8  int LCSLength(string X,
9  {
10     // return if we hav
11     if (m == 0 || n ==
12         return 0;
13
14     // construct a uniq
15     string key = to_str
16
17     // if sub-problem i
18     // store its result
19     if (lookup.find(key
20     {
21         // if last char
22         if (X[m - 1] ==
23             lookup[key]
24
25         else
26             // else if last
27             lookup[key] = m
28     }
29
30     // return the subpr
31     return lookup[key];
32 }
33
34
```

49 }
```

Download
Run
Code

Output:

The length of LCS is 4

The time complexity of above solution is $O(mn)$ and auxiliary space used by the program is $O(mn)$. Note that we can also use array instead of map. Check implementation [here](#).

Above *Memoized* version follows the [top-down approach](#), since we first break the problem into subproblems and then calculate and store values. We can also solve this problem in [bottom-up manner](#). In the bottom-up approach, we calculate the smaller values of $LCS(i, j)$ first, then build larger values from them.

```

1] +
1           if
X[i-1] == Y[j-1]
    | longest(LCS[i
- 1][j], LCS[i][j -
1])    if X[i-1] != Y[j-1]

```

Let X be “XMJYAUZ” and Y be “MZJAWXU”. The longest common subsequence between X and Y is “MJAU”. The table below is generated by the function LCSLength, shows the lengths of the longest common subsequences between prefixes of X and Y. The ith row and jth column shows the length of the LCS of substring $X[0..i-1]$ and $Y[0..j-1]$.

only the solutions to the current row and the previous row.

Applications of LCS problem:

The longest common subsequence problem forms the basis of data comparison programs such as the diff utility and use in field of bioinformatics. It is also widely used by revision control systems such as Git.

Exercise:

1. [Extend the solution for finding length of LCS for K-sequences](#)
2. [Write space optimized code for iterative version.](#)

Recommended Read: [Longest Common Subsequence \(Finding all LCS\)](#)
